Many thanks to the all members of SuperKEKB (Linac/Ring) and MELSC operators.

# First synchrotron injection attempt into the SuperKEKB HER

## Contents

- Introduction
- Why synchrotron injection ?
- Injection commissioning of the synchrotron injection
- Simulations
- Summary

# Injection limits luminosity

The injection status at the peak luminosity record ( $5.24 \times 10^{34}$ ) in March 2026

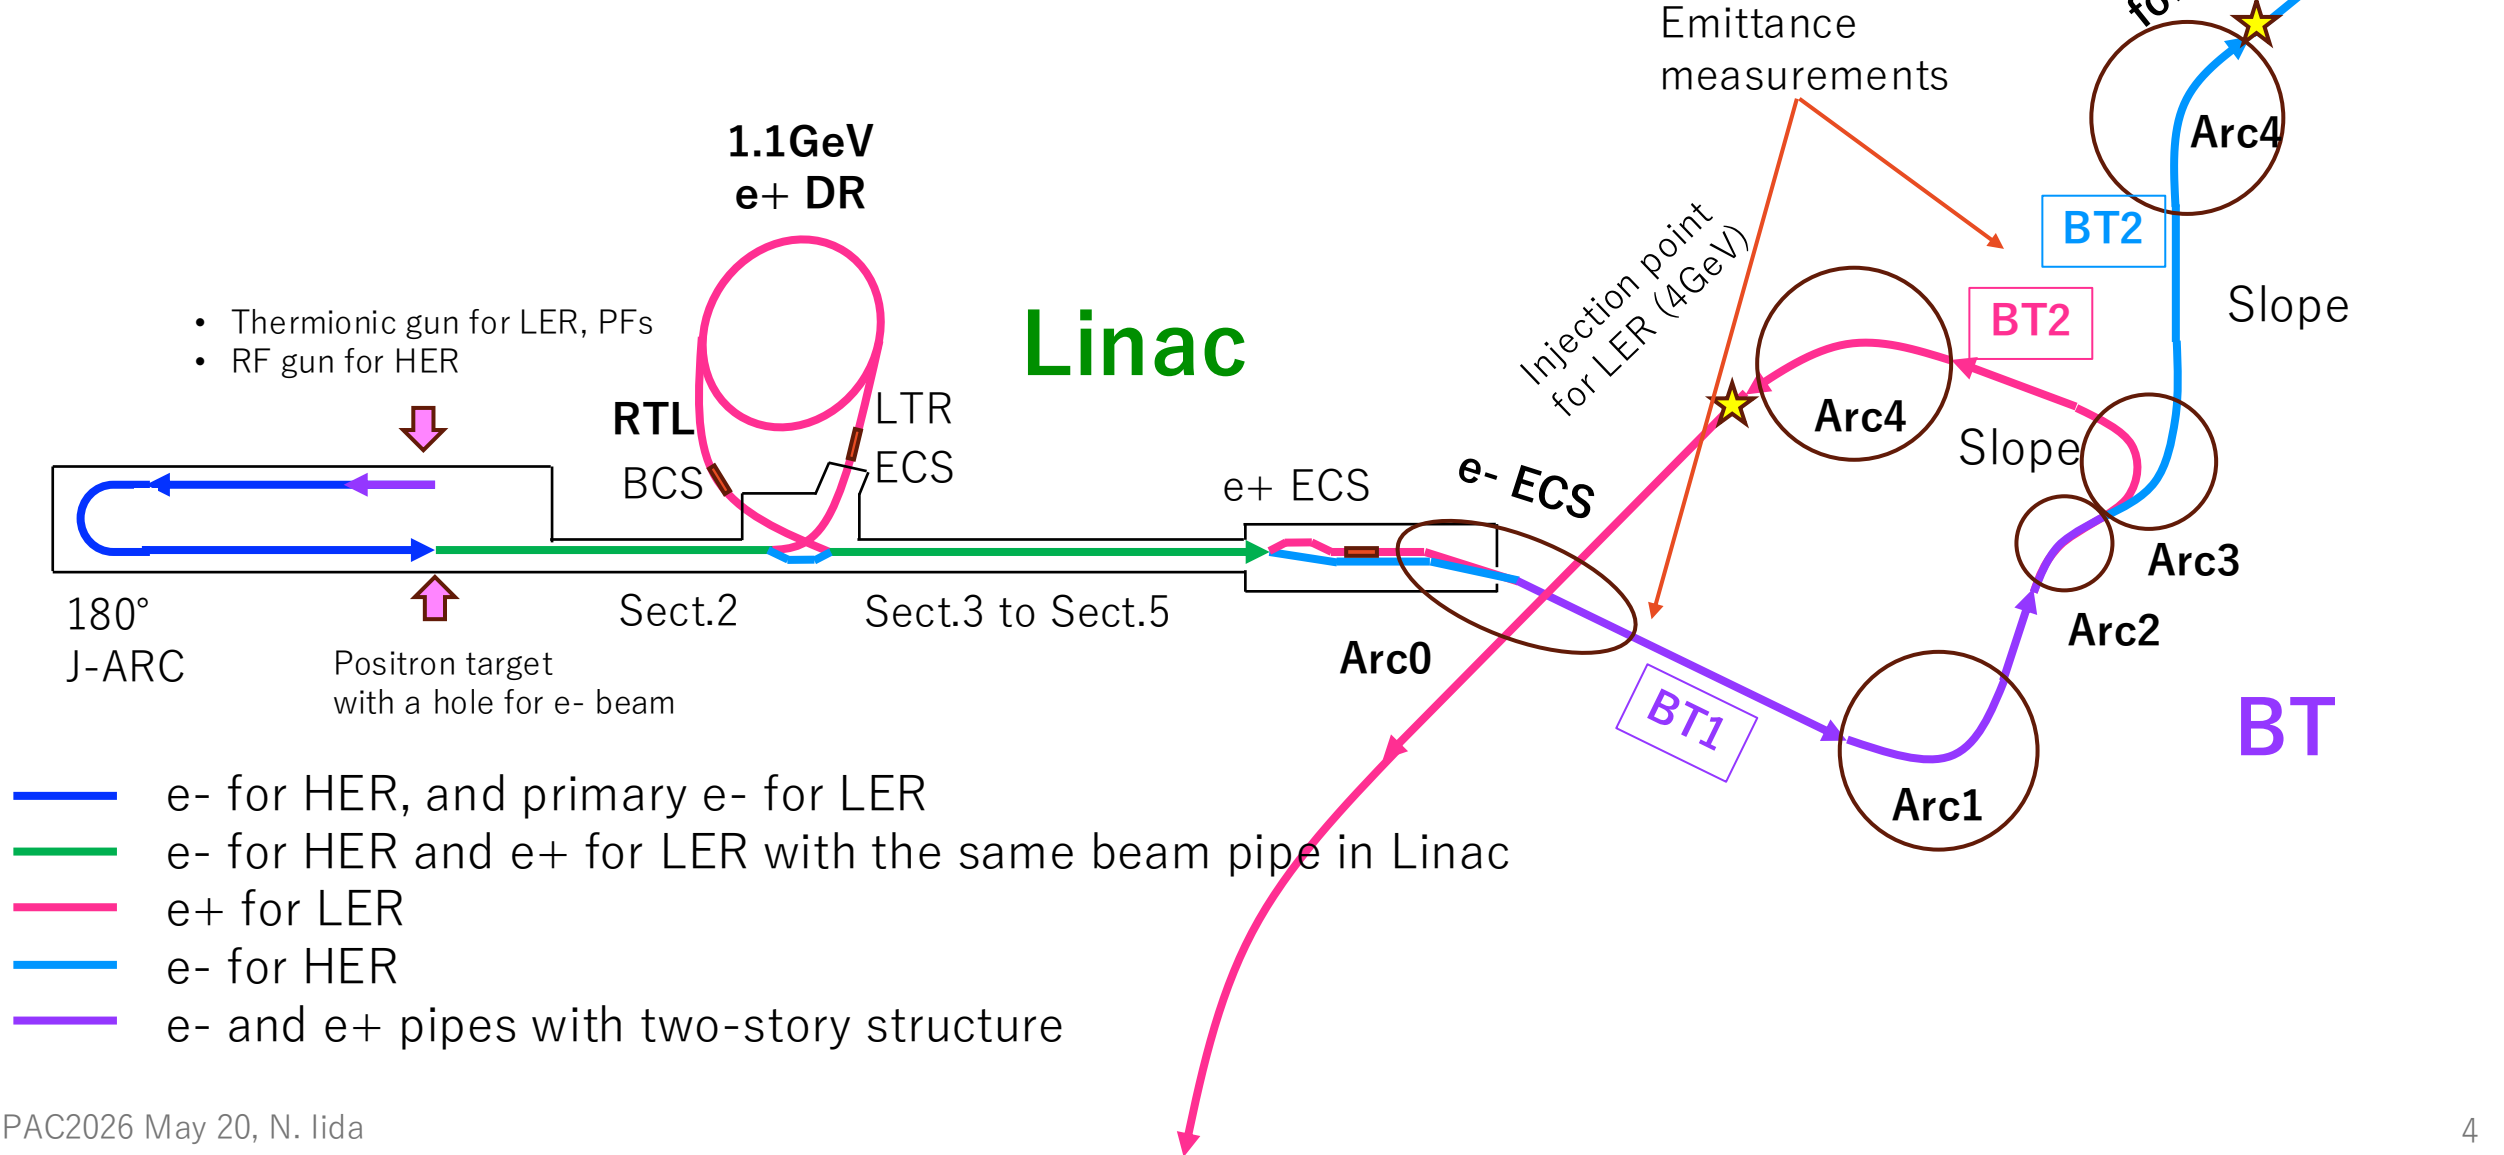

- The stored current was limited by,**
- Linac bunch charge (1.8nC/pulse)
  - Repetition rate (21Hz)
  - Injection efficiency (~50%)
  - Beam lifetime (~12 min)

← Each parameter must be improved for higher luminosity!

# Layout of Injector

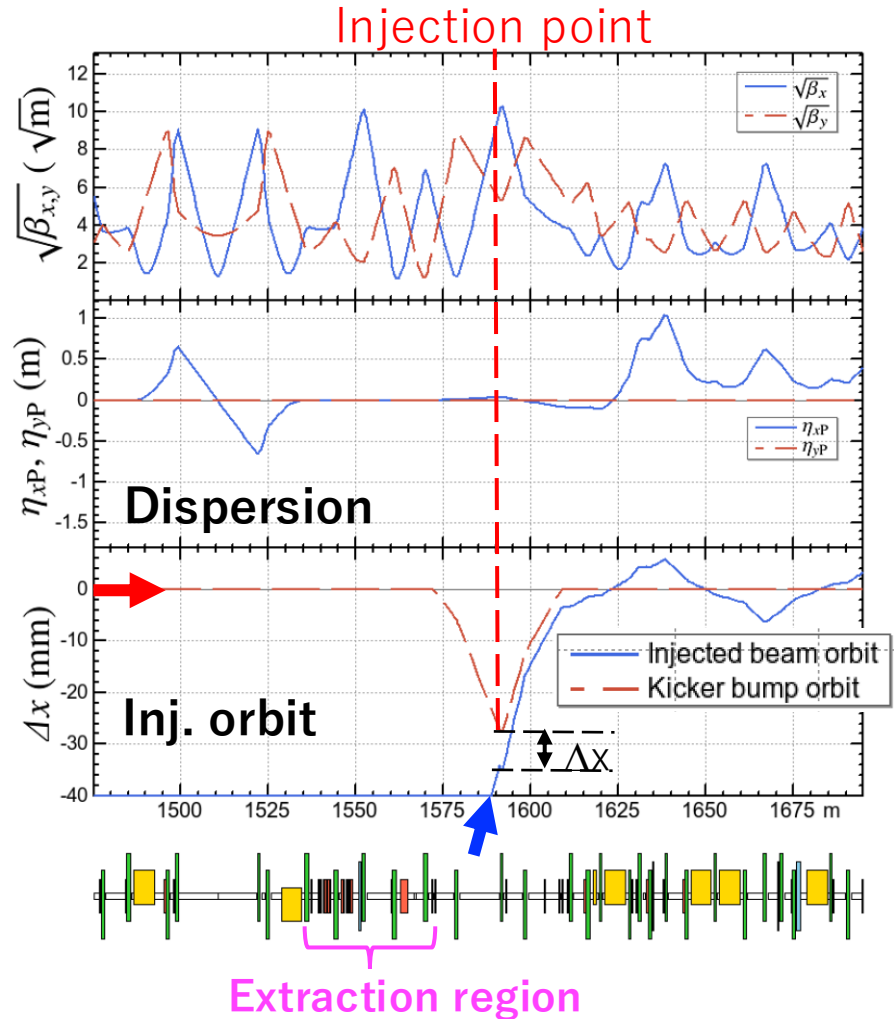

## Linac and BT (Beam Transport line)

# Ring optics for injection

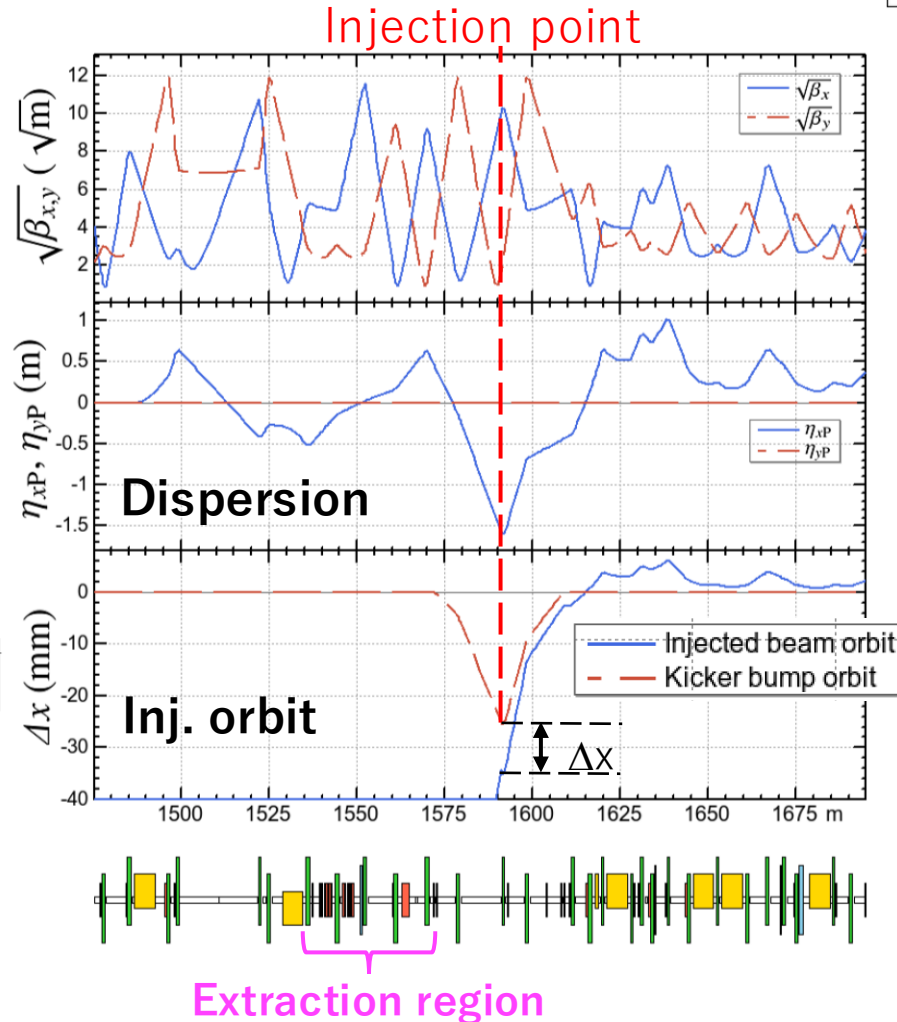

## Betatron injection (BI)

Off axis, on momentum

## Synchrotron injection (SI)

On axis, off momentum

- $\eta_x = \Delta X / \delta$ : horizontal dispersion  
= orbits of the beam with offset energy ( $\delta$ )
- **In SI**, the energy of injection beam is made higher = The injection beam's orbit makes the dispersion orbit. So  $\Delta X = 0$  in the non-dispersive region.  
→  $\Delta X = 0$  at the interaction region.
- However, although it oscillate in the longitudinal direction, its impact on collisions is small.

BI:  $\Delta X = \Delta X_\beta$

SI:  $\Delta X = \eta_x \delta$

# Why synchrotron injection (SI) ?

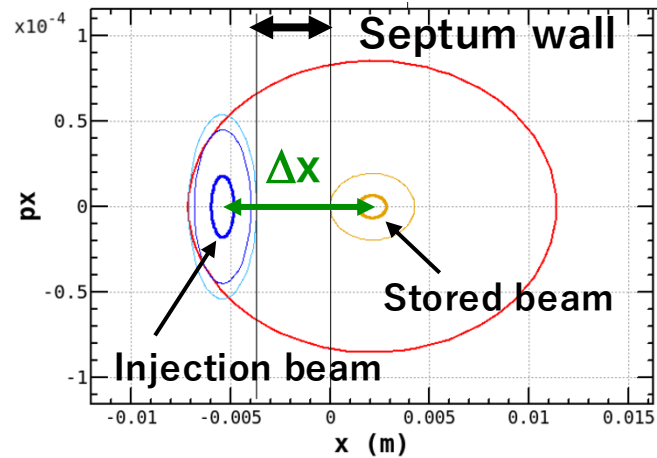

The injection oscillation is converted from the horizontal to the longitudinal in SI.

- The horizontal orbit oscillation in the no-dispersive region became almost eliminated
- **Head-on collision**
  - in general, if the injected beam undergoes **horizontal oscillation** during **top-up injection**, this beam can be kicked by the opposite beam.
- **Nano beam scheme**
  - Furthermore, in the nano-beam scheme, a **large horizontal oscillation** of the injected beam causes collisions to occur at locations with larger  $\beta_y$  at the IP, **resulting in stronger beam-beam kicks** and consequent beam loss. For this reason, synchrotron injection, which suppresses large horizontal injection oscillations, had been considered the design stage.
- **HER Dynamic Aperture(DA))**
  - **The horizontal oscillation** is coupled into vertical oscillation through the x-y coupling in the HER, causing **the beam to approach the vertical dynamical aperture**.
- **Synchrotron lights from injected beam towards the IP**
  - In BI, **synchrotron radiation** generated by **the horizontal injection oscillation** in quadrupole magnets strikes the beam pipe near the central chamber **contributing to the background** in the Belle II detector. In SI, the horizontal injection oscillation is eliminated.
- Shorter damping time
  - The longitudinal damping time is twice shorter than the horizontal one, so it is expected that the Belle II BG will be shorter.
- Vulnerability to sextupole misalignments and tune variation
  - To be confirmed by simulations

# Action of the beams at the injection point

## Betatron injection (BI)

## Synchrotron injection (SI)

## Synchro-beta injection (SBI)

Table 1: Injection Parameters. The subscript  $inj$  denotes the values of ring / injection beams at the virtual injection point PINJAXO.

	BI	SI	SBI
$\varepsilon_x$ [nm]		4.6 / 10.2	
$\sigma_\delta$ [%]		0.063 / 0.18 <sup>1</sup>	
$\beta_{x,inj}$ [m]	108.4 / 31.6	108.4 / 63.9	108.4 / 27.2
$\alpha_{x,inj}$	0 / 0	0 / 0	0 / 0
$\eta_{x,inj}$ [m]	0 / 0	-1.66 / 0	-1.66 / 0
$\eta_{p_x,inj}$ at IP	0 / 0	-0.02 / -0.02	-0.02 / -0.02
$\Delta E / E$ [%]	0.0	+0.6	+0.3
$2J_x$ [ $\mu$ m]	0.79	0.15	0.50

## Survival ratio of injected beam from simulations (%)

	BI	SI	SBI
--	----	----	-----

w/o bb	93.6±0.8	85.6±1.0	77.6 ± 1.3
--------	----------	----------	------------

SI is tested this time.

# Injection commissioning

- Synchrotron injection was tried for SuperKEKB-HER.
  - Nov 6~20, 2025
    - $\beta^*_{x,y}$ 
      - (400, 81) mm, “detuned optics” for **four days** for vacuum scrubbing
      - (200, 8) mm for **two days** for measurement and extraction orbit tuning.
      - (100, 3) mm for **two hours**
      - (60, 1) mm for **14.5 hours collision tuning** and going to the **physics run**
  - Nov 20 10:00, 2025
    - The injection scheme was switched back to the betatron injection, because the test period was over.
      - The injection was worse for the higher repetition rate, 12.5 Hz than 5 Hz.
      - However, this phenomenon often occurs even with BI, so it doesn't seem to be unique to SI.

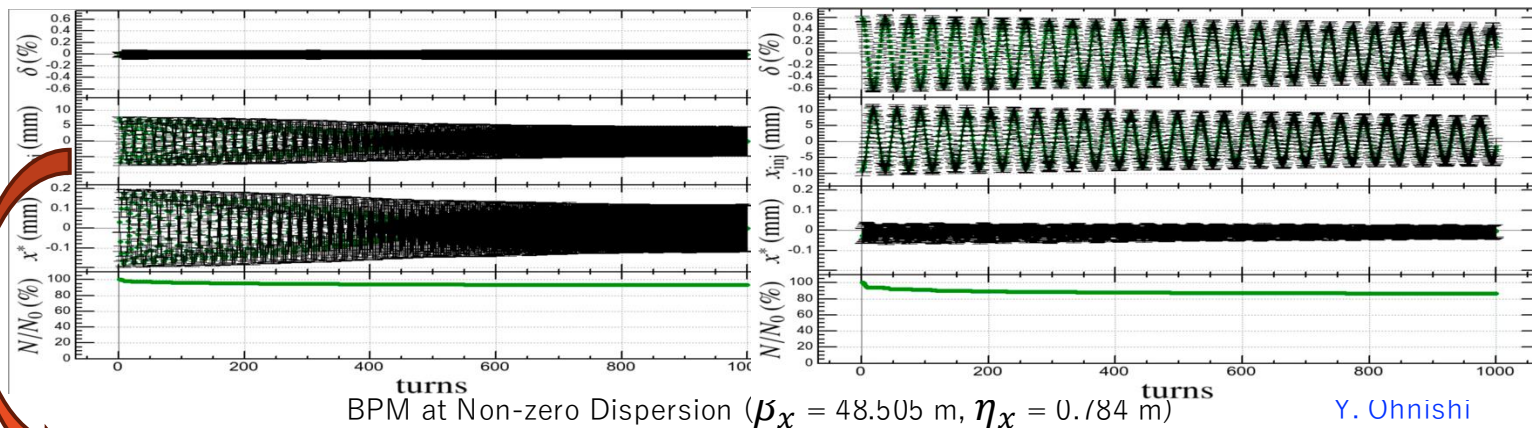

# Oscillation of injected beam

*Complete agreement!*

Simulation

Betatron injection

Synchrotron injection

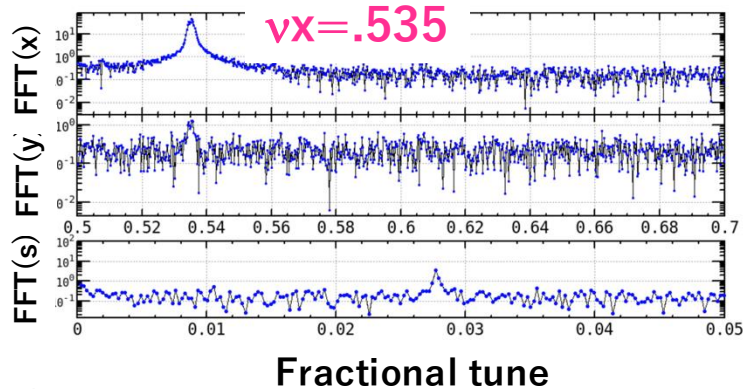

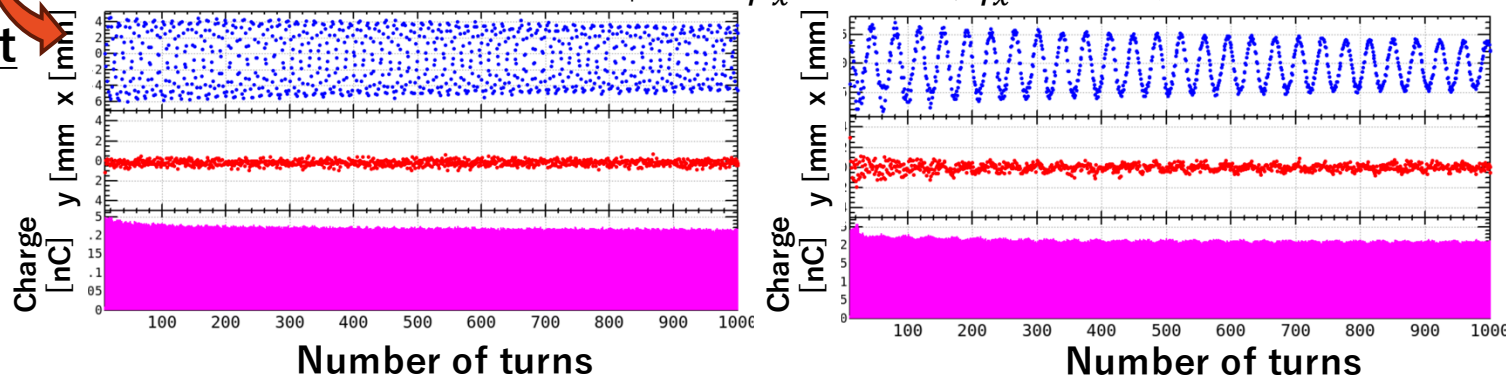

BPM at Non-zero Dispersion ( $\beta_x = 48.505$  m,  $\eta_x = 0.184$  m) Y. Ohnishi

Measurement

by TbT-BPM

$\beta y^* = 81$  mm

(detuned optics)

- During the detuned optics operation, the oscillations of injected beam were measured with the TbT-BPMs.
- **A significant difference in oscillation frequencies** is observed between BI and SI.
- A peak appears at the horizontal tune in the FFT spectrum of BI, while the synchrotron tune of SI.
- These results indicate a **perfect realization of the synchrotron injection**.
- The loss in the first a few turns has been indeed actually observed in the simulation.

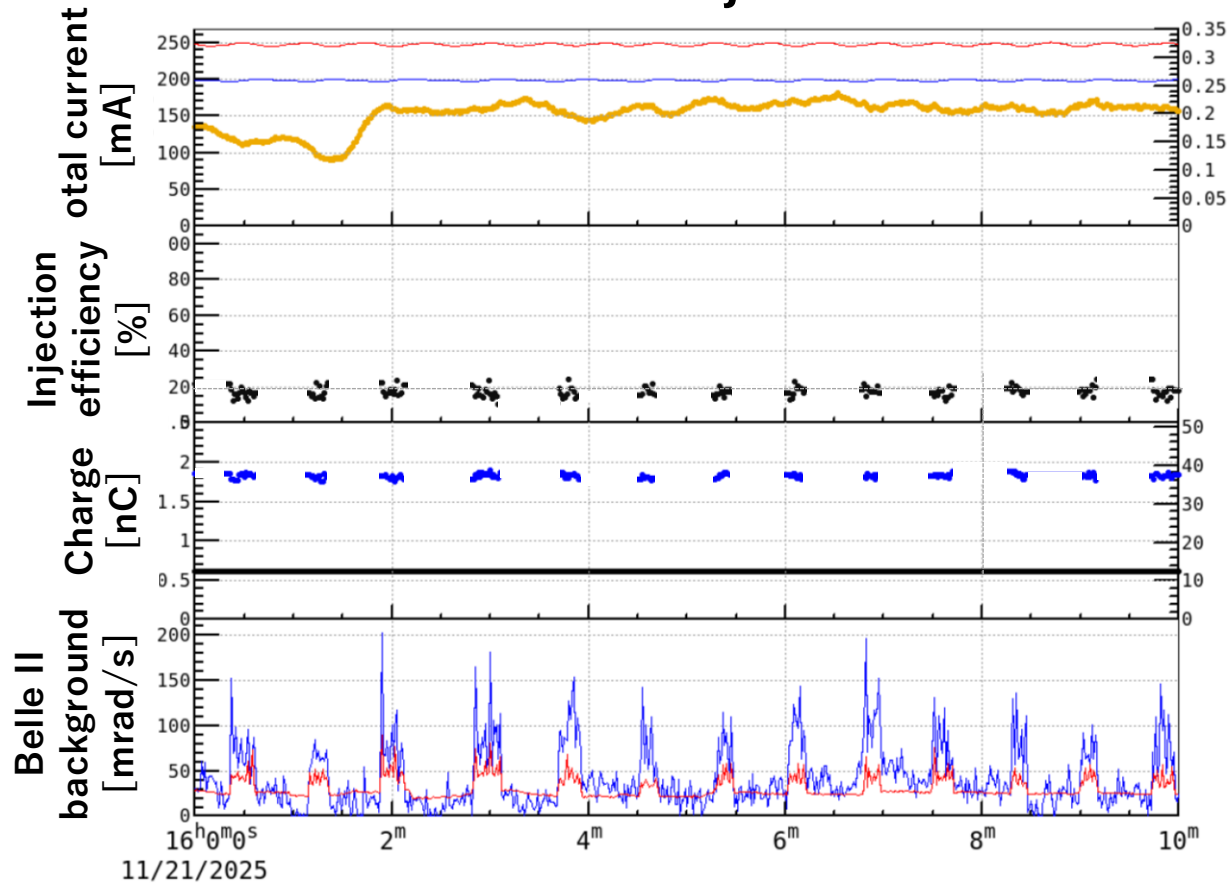

# Injection history of SI and BI in 2025 autumn

Luminosity  
( $10^{34}$ )

The injection efficiency of **SI** was achieved **60 %** only **in 6 hours**, while **BI** could not exceed **20%** even **in 5 days**.

## Betatron injection

## Synchrotron injection

- **In the 2025c run**, since the RF gun for HER e- beam was just changed and for the no enough tuning time, the **emittances of e- beam were quite larger** than the other runs.
- The Belle II backgrounds were almost same for both injections. (In the next run in 2026, the emittance has been tuned well, so the injection efficiency of BI became 80% in maximum.)

# Tracking Simulations

- Injection beam
  - Linac (by SAD)
    - Longitudinal short-range wake
  - BTe (by elegant)
    - Energy compression system (ECS)
    - CSR and ISR
- Optics matching from BTe to HER
  - Artificial matching
    - Match particles from BTe to HER's off-momentum phase space
  - Emittance scaling
    - Emittance blowup from BT1 to BT2 (~x3) has not been understood.
    - An artificial scaling was necessary.
- HER (by SAD)
  - Full 6D tracking with crab-waist optics.
  - Optional weak-strong beam-beam effects
  - No machine errors
  - 1000 to 20000 particles and 1000 to 8000 turns

# Simulation with beam-beam

**SI: Synchrotron Injection**  
**BI: Betatron Injection**

- The simulated dependence of the injection survival ratio on the bunch population of positrons.
- Obtained by tracking with 1000 particles after 8000 turns from injection.
- The intensity  $N_{e^+} = 4.3 \times 10^{10}$  corresponds to the highest luminosity record  $5.24 \times 10^{34} / \text{cm}^2\text{s}$ .

**The stronger beam-beam effect will affect the injection for BI than SI.**

# Simulation with sextupole misalignments

**SI: Synchrotron Injection**  
**BI: Betatron Injection**

Y. Funakoshi

- The simulated dependence of
  - the survival ratio (upper)
  - the vertical emittance (lower)
 by random vertical misalignments for all sextupole magnets ( $\Delta y_{\text{sext,rms}}$ ) in the HER  
 $N_{e^+} = 4.3 \times 10^{10}$ .

**The effect of x-y coupling on beam injection is more pronounced in BI than SI.**

- This result is to be expected, as BI involves larger horizontal betatron oscillations, which may influence beam injection via the x-y coupling, touching the vertical dynamic aperture.
- BI is much more strongly affected by beam-beam interaction and sextupole misalignments than SI.**
- This can be a motivation for SI for higher luminosities.

# Simulation of tune scan of injection survival ratio

**SI: Synchrotron Injection**  
**BI: Betatron Injection**

A beam-beam effect

- $Ne^+ = 9.04 \times 10^{10}$ ,
- (1) **Clear resonance lines  $\nu_x - \nu_y \sim N$  and  $5(\nu_x + \nu_y) \sim N$  are seen only for the BI, which are strengthened by beam-beam.**
- (2) There are strong dark bands if the tunes get **close to half-integer** ( $\{\nu_{x,y}\} \rightarrow 0.5$ ) for SI. The reason for the dark bands is that the optics has **insufficient momentum acceptance** required by SI for  $\{\nu_y\} < \sim 0.55$ . A reconfiguration of the optics in this region seems necessary to have a larger tune space.
- (3) The differences due to beam-beam are visible in both cases, and **stronger in BI than SI.**

# Photons hitting the IP beam pipe

- The number of primary photons from the injected beam was estimated by tracking for the first 30 turns with 20000 particles.
- The IP beam pipe is located at  $\pm 0.1$  m from the IP, and has 10 mm inner radius, tilted to the  $e+$  beam by the half crossing angle 41.5 mrad.
- For **BI**, the number of photons per 1000 electrons per turn and average photon energy were  **$1.65 \pm 0.045$  and  $0.37$  keV**, respectively.
- For **SI**, those were  **$0.69 \pm 0.029$  and  $0.39$  keV**. K. Oide

- Since the Belle II-PXD detector has been turned off due to sudden beam losses, the SR background has not been measured.

# Summary

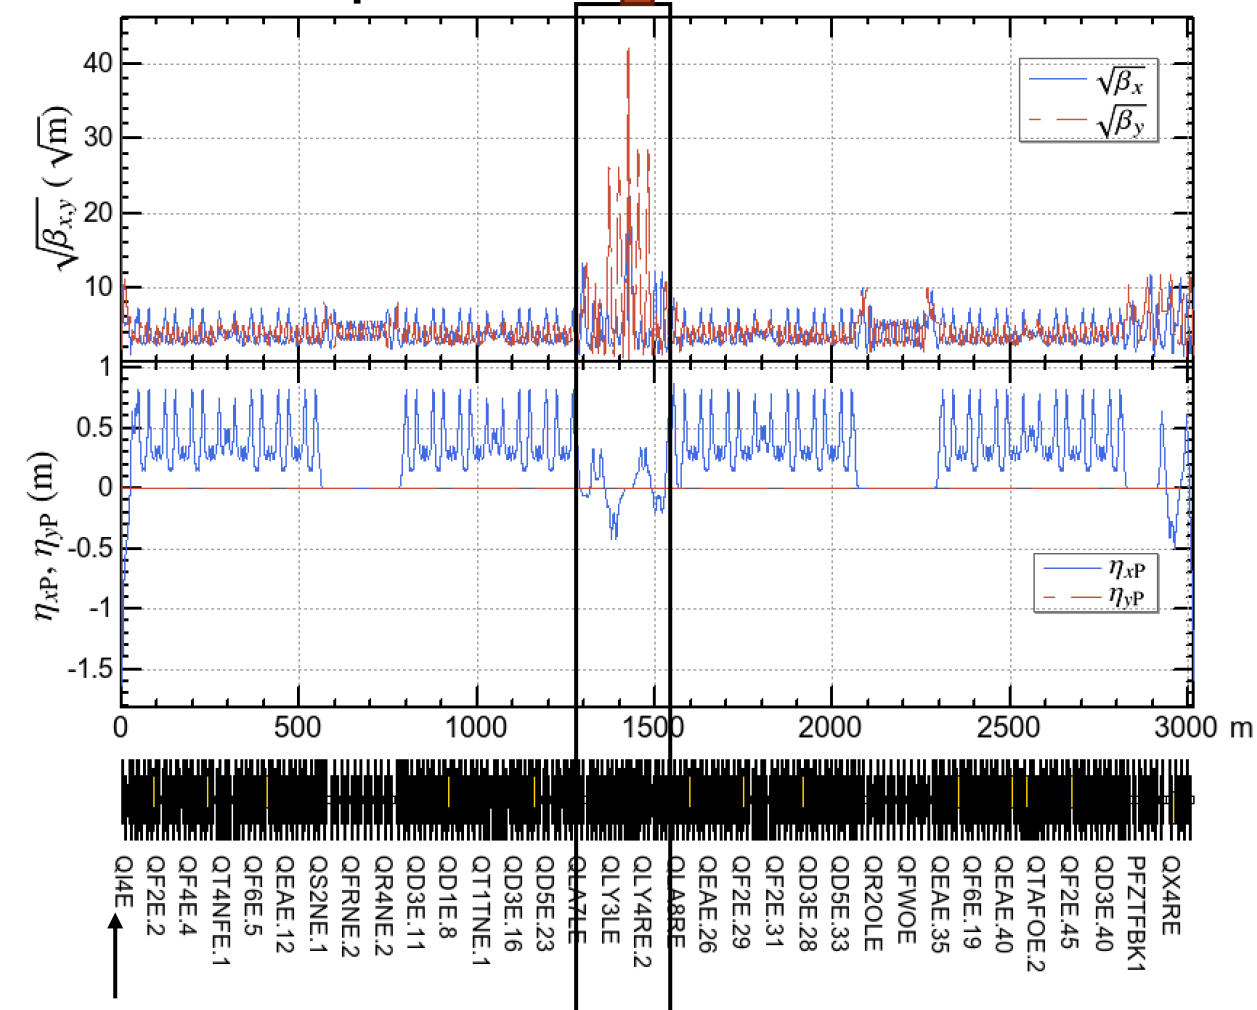

- **Synchrotron injection (SI) was tested for the first time in the HER of SuperKEKB, with collision and top-up.**
- In the experiment, the injection oscillation was **fully transferred** from the horizontal **to the longitudinal plane as designed**, demonstrating the successful SI operation.
- At  $\beta y^* = 1$  mm, **injection tuning was simpler than for BI**, and an **injection efficiency of ~60%** was achieved in 6 hours, while BI did not exceed 20% in 5 days.
  - Although the study was terminated due to injection difficulties at high repetition rates, likely not intrinsic to SI, a future reattempt are planned.
- **Simulations** indicated that **SI is insensitive** to collisions, sextupole misalignments, and betatron tunes.

# HER optics

Injection point

Interaction region

There is no dispersion at the interaction region by design.

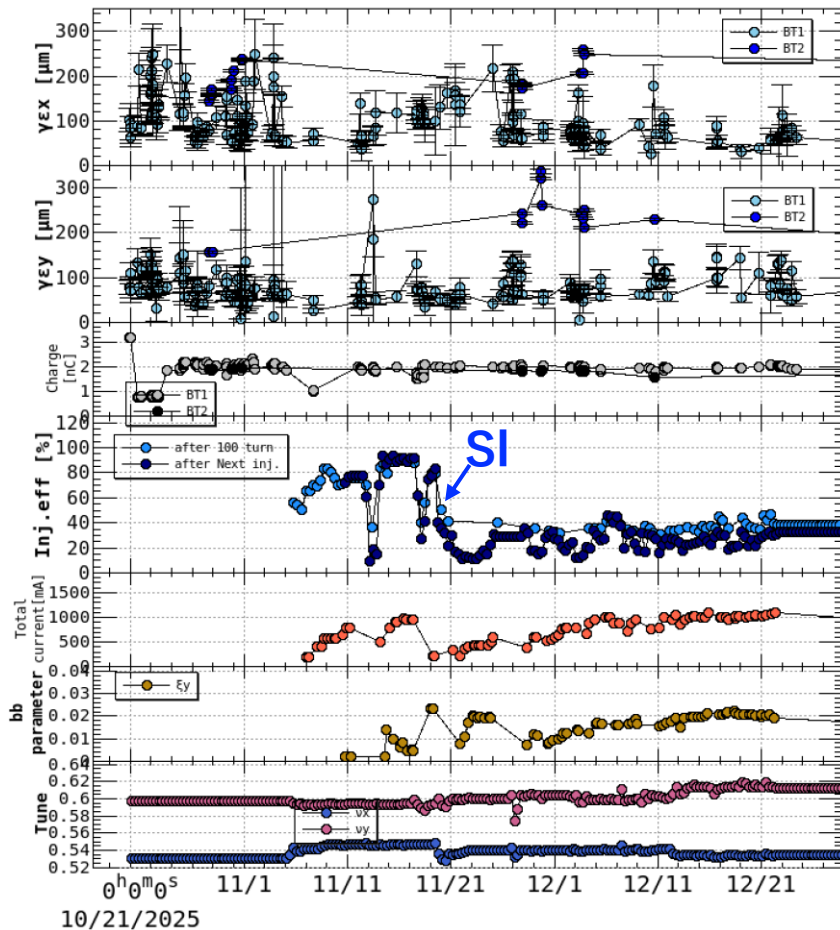

# HER emittances

2024c

e- Measured emittance in BT, Bunch charge, Injection efficiency, and parameters in HER

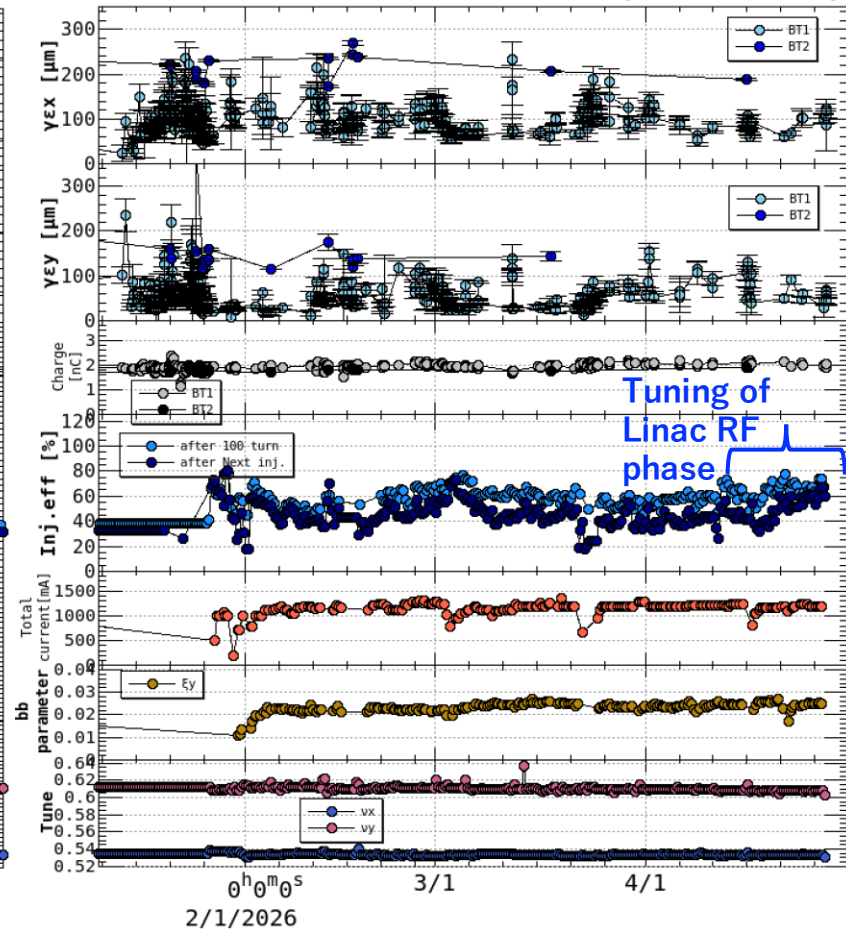

2025c Due to the limited tuning time after the RF replacement, the emittance could not be sufficiently reduced, resulting in poor injection performance throughout the operation.

2026ab

$\gamma\epsilon_y$  has been kept smaller thanks to "EAT" (MOP6653).

2 bunch injection

# Dynamic aperture measurements

**Betatron Injection**

**Synchrotron Injection**

Measured DAs of SI are almost same as those of BI.

Y. Ohnishi

## Horizontal amplitude

## Vertical amplitude

## HER $\beta_y^*$ 1 mm SI optics (2025-11-20)

## HER $\beta_x^*$ 60 mm $\beta_y^*$ 1 mm (2025-11-20)

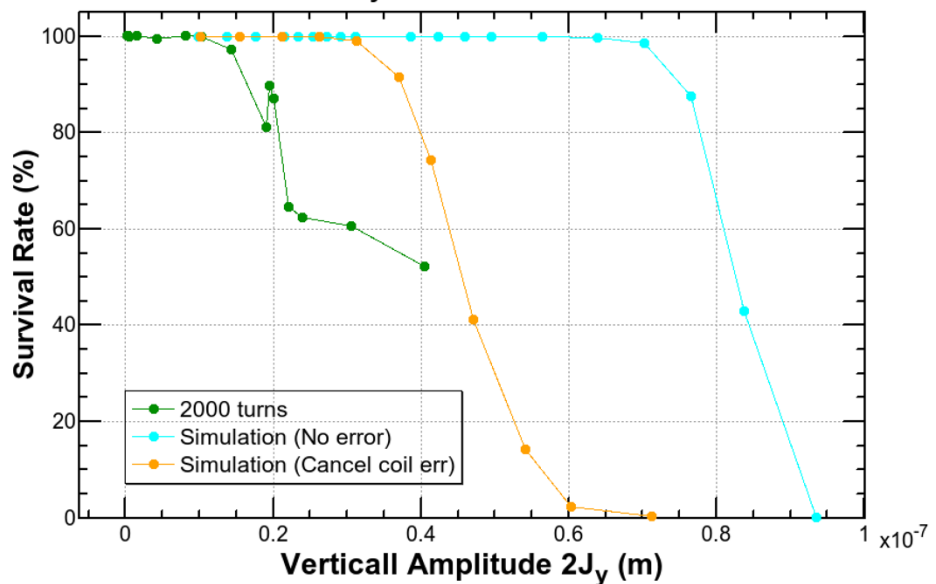

HER  $\beta_y^*$  1 mm (2024-12-18)

HER  $\beta_y^*$  1 mm (2024-12-18)

HER  $\beta_y^*$  1 mm (2024-12-18)

Cancel coil error reduces vertical aperture significantly.

# Tracking simulations of the injection to HER

SI: Synchrotron Injection  
BI: Betatron Injection  
SBI: Synchro-betatron Inj.

K. Oide

- The horizontal amplitude  $x_{inj}$  consists of the synchrotron motion in the case of SI.
- $x_{inj}$  looks smaller for the BI than for the SI.
  - This is because the separation between the stored and injected beams are smaller for the BI. This horizontal displacement at the injection point mostly consists of the synchrotron motion in the case of SI.
- The horizontal oscillation at the IP,  $x^*$ , reaches an amplitude of approximately  $\pm 0.2$  mm in BI, whereas it is suppressed to less than  $\pm 0.05$  mm in SI.
  - This significant reduction in the horizontal injection oscillation suggests that SI provides improved the injection during collision.

	BI	SI	SBI
w/o bb	93.6±0.8	85.6±1.0	77.6 ± 1.3
w bb	91.2±0.8	84.6±1.1	70.9 ± 1.5

- As we did not test SBI.
- For SI, about 5% loss is seen at the first a few turns because that the momentum acceptance is slightly insufficient.

K. Oide

- It is true that the oscillations of both  $\delta$  and  $x$  are smaller when matching is used, and the loss is slightly better when matching is used, but the difference is not significant.
- It is easier to adjust if  $\eta x$  is closed at the septum exit, so I would like to try SI with both  $hx=0$  and  $1.6\text{m}$ .

[II]  $\eta x=-1.6\text{ m}$  at INJECTIO(BT end)  
 The dispersion is matched to HER.

# $\beta y^* = 1\text{mm}$ injection tuning

- A TbT-BPM measurement of the injected beam.
- The horizontal axis shows the turn number, where the injection was performed at the turn #12.
- The points before turn #12 show the previously stored beam, which was kicked out by the injection kickers at turn #12, while the next beam is injected simultaneously.
- The stepwise increase in beam charge indicates that the survival ratio of the previously injected beam was 65%, by assuming the same amount of injected charge.
- The injection phase was adjusted so that the horizontal oscillation at a TbT-BPM in a dispersive region is maximized on the first turn.
- This ensures that the longitudinal oscillation arises solely from the energy difference, i.e., the phase is properly tuned.

However, for some reason, changing the repetition rate of injection from 5Hz to 12.5Hz reduced the injection efficiency and drastically increased the background (BG) of the Belle II detector.

# Injection efficiencies

- A) The injection efficiency in the first approximately 100 Turn is easily affected by the effects of the injection beam (injection adjustment, injection beam emittance, etc.).
- B) From 1000 Turn onwards, it is easily affected by the effects of the ring (tuning, beam-beam).
